Introduction to matrices

Instructor: Paul M. Magwene

Overview of Lecture

- Introduction to Matrices
 - Matrices as collections of vectors
 - Special matrices
- Matrix operations
 - Matrix addition, subtraction
 - Matrix multiplication
 - Transpose
 - More special matrices
- Matrices concepts
- Linear dependence/independence
- Matrix inverses
- Solving simultaneous linear equations
- Multiple regression

Introduction to Matrices

- One way to think about a matrix is as a collection of vectors. This is, in essence, what a multivariate data set is.
- A matrix which has n rows and p columns will be referred to as a $n \times p$ matrix. $n \times p$ is the shape of the matrix.

$$A_{(n \times p)} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1p} \\ a_{21} & a_{22} & \cdots & a_{2p} \\ \vdots & \vdots & \vdots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{np} \end{bmatrix}$$

Special Matrices

■ Zero matrix

$$O = \begin{bmatrix} 0 & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 \end{bmatrix}$$

■ Square matrix

A matrix whose shape is $n \times n$

$$A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix}$$

■ Ones matrix

$$1 = \begin{bmatrix} 1 & 1 & \cdots & 1 \\ 1 & 1 & \cdots & 1 \\ \vdots & \vdots & \ddots & \vdots \\ 1 & 1 & \cdots & 1 \end{bmatrix}$$

■ Diagonal matrix

A square matrix where the off-diagonal elements are zero.

$$A = \begin{bmatrix} a_{11} & 0 & \cdots & 0 \\ 0 & a_{22} & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & a_{nn} \end{bmatrix}$$

Scalar Multiplication of a Matrix

- Let k be a scalar and let A be the matrix

$$A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1p} \\ a_{21} & a_{22} & \cdots & a_{2p} \\ \vdots & \vdots & \vdots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{np} \end{bmatrix}$$

- then

$$kA = \begin{bmatrix} ka_{11} & ka_{12} & \cdots & ka_{1p} \\ ka_{21} & ka_{22} & \cdots & ka_{2p} \\ \vdots & \vdots & \vdots & \vdots \\ ka_{n1} & ka_{n2} & \cdots & ka_{np} \end{bmatrix}$$

Addition and Subtraction of Matrices

- Let A and B be matrices that have the same shape, $n \times p$:

$$A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1p} \\ a_{21} & a_{22} & \cdots & a_{2p} \\ \vdots & \vdots & \vdots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{np} \end{bmatrix} \quad B = \begin{bmatrix} b_{11} & b_{12} & \cdots & b_{1p} \\ b_{21} & b_{22} & \cdots & b_{2p} \\ \vdots & \vdots & \vdots & \vdots \\ b_{n1} & b_{n2} & \cdots & b_{np} \end{bmatrix}$$

- then

$$A + B = \begin{bmatrix} a_{11} + b_{11} & a_{12} + b_{12} & \cdots & a_{1p} + b_{1p} \\ a_{21} + b_{21} & a_{22} + b_{22} & \cdots & a_{2p} + b_{2p} \\ \vdots & \vdots & \vdots & \vdots \\ a_{n1} + b_{n1} & a_{n2} + b_{n2} & \cdots & a_{np} + b_{np} \end{bmatrix}$$

$$A - B = A + (-B)$$

Multiplying a Matrix by a Vector

- Let A be a $n \times p$ matrix, and let \mathbf{x} be a $p \times 1$ column vector

$$A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1p} \\ a_{21} & a_{22} & \cdots & a_{2p} \\ \vdots & \vdots & \vdots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{np} \end{bmatrix} \quad \mathbf{x} = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_p \end{bmatrix}$$

- then

$$A\mathbf{x} = \begin{bmatrix} a_{11}x_1 + a_{12}x_2 + \cdots + a_{1p}x_p \\ a_{21}x_1 + a_{22}x_2 + \cdots + a_{2p}x_p \\ \vdots \\ a_{n1}x_1 + a_{n2}x_2 + \cdots + a_{np}x_p \end{bmatrix}$$

Note that $A\mathbf{x}$ is a vector with shape $n \times 1$. The i -th element of $A\mathbf{x}$ is equivalent to the dot product of the i -th row vector of A with \mathbf{x} .

General Matrix Multiplication

- Let A be a $n \times p$ matrix and B be a $p \times q$ matrix:

$$A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1p} \\ a_{21} & a_{22} & \cdots & a_{2p} \\ \vdots & \vdots & \vdots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{np} \end{bmatrix} \quad B = \begin{bmatrix} b_{11} & b_{12} & \cdots & b_{1q} \\ b_{21} & b_{22} & \cdots & b_{2q} \\ \vdots & \vdots & \vdots & \vdots \\ b_{p1} & b_{p2} & \cdots & b_{pq} \end{bmatrix}$$

- The product AB is an $n \times q$ matrix whose (i, j) -entry is the dot product of the i -th row vector of A and the j -th column vector of B .
- A and B must be conformable to calculate the product AB , i.e. the number of columns in A must be the same as the number of rows in B .

Matrix Arithmetic Rules

- i $A + B = B + A$
- ii $(A + B) + C = A + (B + C)$
- iii $k(A + B) = kA + kB$
- iv $(kA)B = k(AB)$
- v $(AB)C = A(BC)$ (associative)
- vi $A(B + C) = AB + AC$ (distributive)
- vi $(A + B)C = AC + BC$ (distributive)

Alert

Matrix multiplication is not commutative, i.e. $AB \neq BA$ in general.

Be careful when you expand expressions like $(A + B)(A + B)$.

Matrix Transpose

- We denote the transpose of a matrix as A^T
- If A is an $n \times p$ matrix, then A^T is a $p \times n$ matrix where $A_{ji}^T = A_{ij}$
- Transpose rules:
 - $(A^T)^T = A$
 - $(A + B)^T = A^T + B^T$
 - $(AB)^T = B^T A^T$
- Symmetric matrix– square matrix, A , where $A^T = A$

$$A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1p} \\ a_{21} & a_{22} & \cdots & a_{2p} \\ \vdots & \vdots & \vdots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{np} \end{bmatrix}$$

$$A^T = \begin{bmatrix} a_{11} & a_{21} & \cdots & a_{n1} \\ a_{12} & a_{22} & \cdots & a_{n2} \\ \vdots & \vdots & \vdots & \vdots \\ a_{1p} & a_{2p} & \cdots & a_{np} \end{bmatrix}$$

Identity matrix

An identity matrix is a $p \times p$ matrix with ones on the diagonal and zeros everywhere else.

$$I = \begin{bmatrix} 1 & 0 & \cdots & 0 \\ 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 \end{bmatrix}$$

- $IA = AI = A$ if I and A are $n \times p$ matrices
- $A = I\mathbf{x}$ is a diagonal matrix where $a_{ii} = x_i$ if I is an $n \times n$ matrix and \mathbf{x} is a $n \times 1$ vector.

Descriptive statistics as matrix functions

Mean vector and mean matrix

Assume you have a data set represented as a $n \times p$ matrix, X , with observations in rows and variables in columns.

Mean vector

To calculate a row vector of means, $\mathbf{m} = [\bar{X}_1, \bar{X}_2, \dots, \bar{X}_p]$

$$\mathbf{m} = \frac{1}{n} \mathbf{1}^T X$$

where $\mathbf{1}$ is a $n \times 1$ column vector of ones.

Matrix of column means

$$M = \mathbf{1} \mathbf{m}$$

Deviation matrix

To re-express each value as the deviation from the variable means (i.e. each column is a mean centered vector) we calculate a deviation matrix:

$$\mathbf{D} = \mathbf{X} - \mathbf{M}$$

Covariance and correlation matrices

Covariance matrix

$$\mathbf{S} = \frac{1}{n-1} \mathbf{D}^T \mathbf{D}$$

Correlation matrix

$$\mathbf{R} = \mathbf{V} \mathbf{S} \mathbf{V}$$

where \mathbf{V} is a $p \times p$ diagonal matrix where $V_{ii} = 1/\sqrt{S_{ii}}$.

Linear dependence and independence

Linear dependence and independence

- You'll remember that a linear combination of vectors is an equation of the form $z = b_1\mathbf{x}_1 + b_2\mathbf{x}_2 + \cdots + b_p\mathbf{x}_p$
- A list of vectors, $\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_p$, is said to be linearly dependent if there is a non-trivial combination of them which is equal to the zero vector.

$$b_1\mathbf{x}_1 + b_2\mathbf{x}_2 + \cdots + b_p\mathbf{x}_p = \mathbf{0}$$

- A list of vectors that are not linearly dependent are said to be linearly independent

Matrix Inverses

- If A is a square matrix and C is a matrix of the same size where $AC = I$ and $CA = I$ then C is the inverse of A and we denote it as A^{-1} .

$$AA^{-1} = A^{-1}A = I$$

- Rules for inverses:
 - Only square matrices are invertible; but not every square matrix can be inverted
 - A matrix for which we can find an inverse is called invertible (non-singular)
 - A matrix for which no inverse exists is singular (non-invertible)
 - Any diagonal matrix, A , where the a_{ii} are non-zero, is invertible
 - If A and B are both invertible $p \times p$ matrices then $(AB)^{-1} = B^{-1}A^{-1}$ (note change in order).

Highlight

If a matrix is invertible then its columns form a linearly independent list of vectors!

Simultaneous Linear Equations

Simultaneous Linear Equations

- A set of simultaneous linear equations are equations like the following:

$$x_1 + 3x_2 + 2x_3 = 3$$

$$-x_1 + x_2 + 2x_3 = -2$$

$$2x_1 + 4x_2 - 2x_3 = 10$$

- Simultaneous linear equations have either:
 - No solutions
 - One solution
 - Infinitely many solutions

Matrices and Simultaneous Linear Equations

- Matrices can be used to represent and solve simultaneous linear equations. For example,

$$\begin{aligned}x_1 + 3x_2 + 2x_3 &= 3 \\ -x_1 + x_2 + 2x_3 &= -2 \\ 2x_1 + 4x_2 - 2x_3 &= 10\end{aligned}$$

Can be represented by the equation $A\mathbf{x} = \mathbf{h}$:

$$\begin{bmatrix} 1 & 3 & 2 \\ -1 & 1 & 2 \\ 2 & 4 & -2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 3 \\ -2 \\ 10 \end{bmatrix}$$

- Solve this equation by pre-multiplying both sides of the equation by A^{-1} .

$$\begin{aligned}A^{-1}A\mathbf{x} &= A^{-1}\mathbf{h} \\ \mathbf{x} &= A^{-1}\mathbf{h}\end{aligned}$$

Simultaneous Equations and Matrix Inverses

- $A\mathbf{x} = \mathbf{h}$ has a unique solution iff A is invertible.
- If A is a singular matrix then $A\mathbf{x} = \mathbf{h}$ either has no solution or infinitely many solutions.

Multiple regression

Variable space view of multiple regression

Figure 4.1: *The regression of Y onto X_1 and X_2 as a scatterplot in variable space.*

Subject Space Geometry of Multiple Regression

Multiple Regression

Let \mathbf{y} be a vector of values for the outcome variable. Let \mathbf{X}_i be explanatory variables.

The regression model is:

$$\mathbf{y} = \hat{\mathbf{y}} + \mathbf{e}$$

where

$$\hat{\mathbf{y}} = a\mathbf{1} + b_1\mathbf{X}_1 + b_2\mathbf{X}_2 + \cdots + b_p\mathbf{X}_p$$

Note that $\hat{\mathbf{y}}$ is a linear combination of the column vectors of \mathbf{X}_i .

Matrix representation of multiple regression

$$\mathbf{y} = \hat{\mathbf{y}} + \mathbf{e}$$

looks like:

$$\begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix} = \begin{bmatrix} \hat{y}_1 \\ \hat{y}_2 \\ \vdots \\ \hat{y}_n \end{bmatrix} + \begin{bmatrix} e_1 \\ e_2 \\ \vdots \\ e_n \end{bmatrix}$$

We can solve for $\hat{\mathbf{y}}$ as:

$$\hat{\mathbf{y}} = \mathbf{X}\mathbf{b}$$

where

$$\mathbf{X} = \begin{bmatrix} 1 & x_{11} & x_{12} & \cdots & x_{1p} \\ 1 & x_{21} & x_{22} & \cdots & x_{2p} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & x_{n1} & x_{n2} & \cdots & x_{np} \end{bmatrix} ; \mathbf{b} = \begin{bmatrix} a \\ b_1 \\ b_2 \\ \vdots \\ b_p \end{bmatrix}$$

Finding the Multiple Regression Coefficients

How do we solve for \mathbf{b} in $\hat{\mathbf{y}} = \mathbf{X}\mathbf{b}$?

Estimate \mathbf{b} as:

$$\mathbf{b} = (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \mathbf{y}$$

Compare this to our formula for estimating the coefficient b in the bivariate regression of $\vec{\mathbf{y}}$ on a single variable $\vec{\mathbf{x}}$:

$$b = \frac{\vec{\mathbf{x}} \cdot \vec{\mathbf{y}}}{\vec{\mathbf{x}} \cdot \vec{\mathbf{x}}}$$

Multiple Regression “Loadings”

In addition to the regression coefficients, the regression “loadings” – the cosine of the angle between vectors that represent the explanatory variables and the prediction vector – are also very useful for interpreting the regression model.

Individual loadings can be calculated as:

$$\cos \theta_{\vec{x}_j, \vec{\hat{y}}} = \frac{\vec{x}_j \cdot \vec{\hat{y}}}{|\vec{x}_j| |\vec{\hat{y}}|}$$

Multiple Regression, Goodness of fit

As with bivariate regression, we quantify goodness of of the regression model using the coefficient of determination.

The ‘multiple correlation coefficient’ R is defined as:

$$R = \cos \theta_{y, \hat{y}} = \frac{|\hat{y}|}{|y|}$$

and the coefficient of determination, R^2 is:

$$R^2 = \frac{|\hat{y}|^2}{|y|^2}$$

Multiple regression: Cautions and Tips

- Comparing the size of regression coefficients only makes sense if all the predictor variables have the same scale
- The predictor variables (columns of \mathbf{X}) must be linearly independent; when they're not the variables are multicollinear
- Predictor variables that are nearly multicollinear are, perhaps, even more difficult to deal with

Why is near multicollinearity of the predictors a problem?

(a) Non-collinear predictors

(b) Non-collinear predictors

Figure: When predictors are nearly collinear, small differences in the vectors can result in large differences in the estimated regression.

What can I do if my predictors are (nearly) collinear?

- Drop some of the linearly dependent sets of predictors.
- Replace the linearly dependent predictors with a combined variable.
- Define orthogonal predictors, via linear combinations of the original variables (PC regression approach)
- ‘Tweak’ the predictor variables so that they’re no longer multicollinear (Ridge regression).
